 - Do we live in a small world?
- 5 Challenge

What are networks?

- Networks are a representation of **interaction structure** among units.

In the case of social and economic networks, these units (nodes) are individuals or firms.

- At some broad level, the study of networks can encompass the study of all kinds of interactions.

Example 1: Internet

- Node: webpage.
- Link: (directed) link.

Example 1: Internet (Cont.)

- How does Google Search work?
- **PageRank** is an algorithm used by Google Search to rank websites in their search engine results.
- PageRank is a way of measuring the importance of website pages.
- PageRank was named after **Larry Page**, one of the founders of Google.

Example 2: Political blogs

The network structure of political blogs prior to the 2004 U.S. Presidential election reveals two natural and well-separated clusters (Adamic and Glance, 2005)

Example 3: Seven Bridges of Königsberg (Cont.)

- The **Seven Bridges of Königsberg** is a historically notable problem in mathematics.
- The city of Königsberg in Prussia (now Kaliningrad, Russia) was set on both sides of the Pregel River, and included two large islands (Kneiphof and Lomse) which were connected to each other, or to the two mainland portions of the city, by seven bridges. The problem was to devise a walk through the city that would cross each of those bridges once and only once.
- Its negative resolution by **Leonhard Euler** in 1736 laid the foundations of graph theory and prefigured the idea of topology.

Example 4: Network of friendship

- Node: individual.
- Link: friendship.

The social network of friendships within a 34-person karate club provides clues to the fault lines that eventually split the club apart (Zachary, 1977)

Example 4: Network of friendship (Cont.)

- How to sell a new product?
- Is traditional approach (study possible buyers, advertise, price) good?

Example 5: Financial network

- Node: bank/country.
- Link: debt relationship.

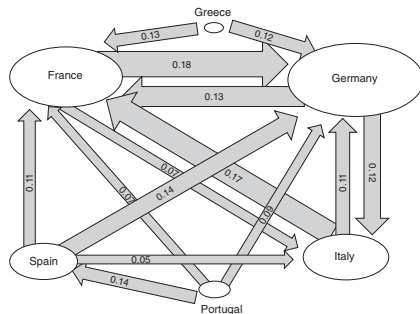

Figure: European debt cross-holdings (Elliott, Golub and Jackson, 2014)

Example 5: Financial network

- Why did the [Federal Reserve](#) take over [American International Group](#) in Financial Crisis 2007–2008?
- Too big to fail or too connected to fail?
- How to control the financial risk?
- More links?
- Equal weight on each link?

Example 6: Spread of disease

- Node: individual.
- Link: contact between individuals.

Figure: The spread of tuberculosis

Example 6: Spread of disease (Cont.)

- How does a contagious disease spread through a population?
- How to deal with the spread of disease?
- Key nodes?

- 1 What are networks?
- 2 Why study networks?
- 3 How to study networks?
- 4 Examples
 - Florentine marriages
 - The rise of Moscow
 - Do we live in a small world?
- 5 Challenge

Why study networks?

Many economic, political, and social interactions are shaped by the **local structure** of relationships:

- trade of goods and services, most markets are not centralized...
- sharing of information, favors, risk...
- transmission of viruses, opinions...
- access to info about jobs...
- choices of behavior, education...
- political alliances, trade alliances...

Why study networks? (Cont.)

Social networks **influence behavior**:

- Will you lend money to your friend? Will you follow their advice? Will you imitate their behavior? Will you trade with other firms that you are potentially “connected to”?
- crime, employment, human capital, voting, smoking...
- networks exhibit heterogeneity, but also have enough underlying structure to model.

Example: Networks in labor markets

Myers and Shultz (1951) for textile workers:

- 62% first job from contact.
- 23% by direct application.
- 15% by agency, ads, etc.

Example: Crimes

- Criminality is often a social behavior and accounting for peer influences and networks of interactions can lead to more effective policies aimed at reducing crime.
- Reiss (1980, 1988): 2/3 of criminals commit crimes with others.
- Glaeser, Sacerdote and Scheinkman (1996): social interaction important in petty crime, among youths, and in areas with less intact households.

Example: Immobility and inequality

- **Persistent inequality** on a number of dimensions (e.g., wages, promotions, health, etc.) between ethnicities, genders, and other social classes is observed.
- Important components of these differences relate to **segregation patterns in interaction**, as segregation in network structures affects how information flows, what access individuals have to various opportunities, and how decisions are made.
- The **underlying social networks** exhibit patterns that can result in persistent inequality and poverty traps.

Example: Others

- Enhancing new technology adoption requires a proper understanding of how peoples' opinions and beliefs are shaped by **word-of-mouth communication**.
- Sustaining informal risk sharing and favor exchange depends on social norms and sanctions, and social structure provides new insights into how communities overcome basic incentive problems.

- 1 What are networks?
- 2 Why study networks?
- 3 How to study networks?
- 4 Examples
 - Florentine marriages
 - The rise of Moscow
 - Do we live in a small world?
- 5 Challenge

Primary questions

- What do we know about network structure?
 - What are the commonalities in different (social, economic and other) networks?
 - How to characterize networks?
- How do networks form? Do the “right” networks form?
 - Why are flight networks in hub-spoke pattern?
 - Why small world?
- How do networks influence behavior? (and vice versa)
 - Diffusion of new technologies and spread of epidemics have certain common features when one looks at their dynamics. Does this mean that they obey the same logic?
 - Why homophily?

Three areas

- Theory
 - network formation, dynamics, design...
 - how networks influence behavior
 - coevolution?
- Empirical and experimental work
 - observe networks, patterns, influence
 - test theory and identify regularities
- Methodology
 - how to measure and analyze networks

Main models

Models for analyzing and understanding networks:

- Random graph methods
- Strategic, game theoretic techniques
- Hybrids, statistical models

Goals

- Presume no prior knowledge on network
- Introduce you to a variety of approaches to modeling networks (more breadth than depth)
- Give a sense of different disciplines' techniques and perspectives

Goals (Cont.)

- Provide insight into why we see certain phenomena
 - Why do social networks have short average path lengths?
- Allow for comparative statics
 - How does component structure change with density?
Important in contagion/diffusion/learning...
- Predict out of sample
 - What will happen with a new policy (vaccine, R&D subsidy, ...)?
- Allow for statistical estimation
 - Is there significant clustering on a local level or did it appear at random?

5 Challenge

1 What are networks?

2 Why study networks?

3 How to study networks?

4 **Examples**

- **Florentine marriages**
- The rise of Moscow
- Do we live in a small world?

5 Challenge

Florentine marriages: Background

- The Medicis emerged as the most influential family in 15th century Florence. **Cosimo de' Medici** (科西莫·德·美第奇) ultimately formed the most politically powerful and economically prosperous family in Florence, dominating Mediterranean trade.
- The Medicis, to start with, were less powerful than many other important families, both in terms of political dominance of Florentine institutions and economic wealth.
- How did they achieve their prominence?
- It could just be luck (in social science, we have to be very careful to distinguish luck from a systematic pattern, and correlation from causation).

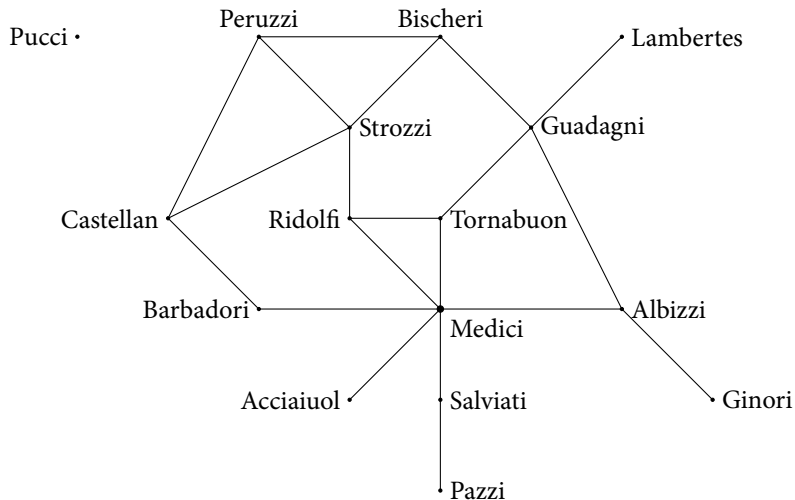

Florentine marriages: Network?

- If one examines wealth and political clout, the Medici did not stand out at this point.

For instance, the Strozzi had both greater wealth and more seats in the local legislature, and yet the Medici rose to eclipse them.

- ⇒ One has to look at the **structure of social relationships** to understand why it was the Medici who rose in power.
- Padgett and Ansell (1993) provide powerful evidence for this by documenting the network of marriages between some key families in Florence in the 1430's.

Florentine marriages: Marriage network

Florentine marriages: Degree

If we do a rough calculation of importance in the network, simply by counting **how many families a given family is linked to** through marriages, then the Medici do come out on top.

- The Medici: 6
- The Strozzi and the Guadagni: 4
- However, the difference is **not significant**.

Florentine marriages: Betweenness

- Let $P(ij)$ denote the **number of the shortest paths** connecting family i to family j .
Let $P_k(ij)$ denote the number of these paths that **family k lies on**.
- The shortest path between the Barbadori and Guadagni has three links in it.

There are two such paths: Barbadori - Medici - Albizzi - Guadagni, and Barbadori - Medici - Tournabouni - Guadagni.
The Medici lie on both paths.

Florentine marriages: Betweenness (Cont.)

- In order to get a fuller feel for how central a family is, we can look at an average of the betweenness calculation.
 - For **each pair** of other families, compute the fraction of the total number of shortest paths between the two given family lies on.
 - Then **averaging across all pairs** of other families gives us a sort of betweenness (or power measure) for a given family.
- For each family k , we calculate

$$\sum_{i,j: i \neq j, i \neq k, j \neq k} \frac{P_k(ij)/P(ij)}{\binom{n}{2}}.$$

If there are no paths connecting i and j , we set $P_k(ij)/P(ij) = 0$.

Florentine marriages: Betweenness (Cont.)

- This measure of betweenness for
 - the Medici: 0.522,
 - the Strozzi: 0.103,
 - the Guadagni: 0.255.
- Padgett and Ansell (1993): “Medician political control was produced by network disjunctures within the elite, which the Medici alone spanned.”

Florentine marriages: Summary

- This analysis shows that network structure can provide important insights beyond those found in other political and economic characteristics.
- The example also illustrates that the network structure is important beyond a simple count of how many social ties each member has, and suggests that **different measures of betweenness or centrality** will capture **different aspects** of network structure.
- Several questions:
 - Was it simply by chance that the Medici came to have such a special position in the network or was it by choice and careful planning?
 - Why did other families not form more ties, or try to circumvent the central position of the Medici?
 - Was the resulting network optimal from a variety of perspectives?

1 What are networks?

2 Why study networks?

3 How to study networks?

4 **Examples**

- Florentine marriages
- **The rise of Moscow**
- Do we live in a small world?

5 Challenge

Why is Moscow the capital of Grand Duchy of Moscow

Why is Moscow the capital of Grand Duchy of Moscow (Cont.)

- The geographic location of Moscow may not be good.
- The degree centrality of Moscow is ranking 5 among 39 cities.

The rise of Moscow

- Forrest R. Pitts, [The medieval river trade network of Russia revisited](#), *Social Networks*, 1978.
- Medieval trade and communication along the **rivers** of Russia are considered as a social network.
- An intermediate node occurrence rate provides a measure of centrality.
- The short-path distances to all other places are summed to provide a system-effort measure of accessibility.
- Both measures show Moscow to have been most central and accessible with aggregate least effort.

- 1 What are networks?
- 2 Why study networks?
- 3 How to study networks?
- 4 Examples**
 - Florentine marriages
 - The rise of Moscow
 - Do we live in a small world?**
- 5 Challenge

Do we live in a small world: Background

- Early 20th century Hungarian poet and writer Frigyes Karinthy first came up with the idea that we live in “small world”. He suggested, in a play, that any two people among the one and a half billion inhabitants of the earth then were linked through **at most five acquaintances**.
- The sociologist **Stanley Milgram** made this famous in his study “**The Small World Problem**” (1967)—though this study is now largely discredited.

Do we live in a small world: Background (Cont.)

- He asked certain residents of Wichita and Omaha to contact and send a folder to a target person by sending it to an acquaintance, who would then do likewise etc., until the target person was reached. This would allow Milgram to measure how many “intermediate nodes” would be necessary to link the original sender and the target.
- 42 of the 160 letters supposedly made it to their target, with a median number of intermediates equal to 5.5.

Do we live in a small world

- Hence was born the idea of [six degrees of separation](#).
- Can you think why Milgram's procedure could give misleading results? Or why we may not wish to take these results on faith?
- There are similar studies for other types of networks. For example, Albert, Jeong, and Barabási (1999) "[Diameter of the World Wide Web](#)" estimated that in 1998 it took on average 11 clicks to go from one random website to another (at the time there were 800 million websites).
- What do these kind of "small world" results imply?

Interpreting small worlds

- Suppose that each node has λ neighbors (e.g., each website has links to λ other websites).
- Each of my λ neighbors will then have λ neighbors themselves.
- Suppose (unrealistically) that my neighbors don't have any neighbors in common (i.e., the λ websites that are linked to my website are not linked among themselves). Then in two steps, I can reach λ^2 other nodes.

Interpreting small worlds (Cont.)

- Repeating the same reasoning (and maintaining the same unrealistic assumption), in d steps I can reach λ^d other nodes.
- Now imagine that this network has $n = \lambda^d$ nodes.
- This implies that the “degrees of separation” (average distance) is

$$d = \frac{\ln n}{\ln \lambda}.$$

- The Karinthy conjecture, under the Poisson assumption, would require that each person should have had approximately 68 “independent” friends.

$$e^{\ln(1,500,000,000)/5} \approx 68.5.$$

Interpreting small worlds (Cont.)

- But our unrealistic assumption rules out the reasonable triadic relations and clustering phenomena, which are common both in social networks, web links, and other networks.

- Interestingly, however, in **Poisson (Erdős-Rényi) random graphs**, we will see that average distance can be approximated for large n by $d = \frac{\ln n}{\ln \lambda}$ (where λ is the expected degree of a node).
- This is because triadic relations shown in the figure are relatively rare in such graphs.

Interpreting small worlds (Cont.)

- This last result in fact can be interpreted as stating that Poisson (Erdős-Rényi) random graphs, though mathematically convenient, will not be good approximations to social networks.
- Instead, most people would be connected to others in remote parts through “special links” (or “connectors”), such as their political representatives, village head, or cousin in a different city etc.
- **Models of small world networks** try to capture this pattern (albeit not always perfectly).

- 1 What are networks?
- 2 Why study networks?
- 3 How to study networks?
- 4 Examples
 - Florentine marriages
 - The rise of Moscow
 - Do we live in a small world?
- 5 Challenge

Challenge

- The number of nodes could be very large.

Challenge (Cont.)

- How many networks on just 30 nodes?
- Person 1 could have 29 possible links, person 2 could have 28 not counting 1, ..., total = 435.
- So 435 possible links, each could either be present or not, so 2^{435} networks.

Challenge (Cont.)

- Diffusion/Learning: local change \rightarrow global change.
- Feedback.
- Coevolution.
